# Introduction

Introduction

**Topic**

Considerations  
about the forms  
Conic optimization.  
A recap  
Basic cone types  
Comments

An illustrative  
example

Algorithms

Given a convex optimization problem then is the **classical** form

$$\begin{array}{ll} \min & c(x) \\ \text{st} & a(x) \geq 0 \end{array}$$

or the **conic** form

$$\begin{array}{ll} \min & c^T x \\ \text{st} & Ax = b, \\ & x \in K. \end{array}$$

preferable from an user perspective?

Assumptions

- $c(x)$  is convex and  $a(x)$  is concave.
- $K$  is a convex cone.
- We can only solve convex problems efficiently.

Introduction

---

Topic

Considerations  
about the forms

Conic optimization.

A recap

Basic cone types

Comments

An illustrative  
example

---

Algorithms

---

- Robustness.
  - ◆ Accuracy of the solution.
  - ◆ How sensitive is the optimizer to the problem data.
- Solution time.
- Does the form help the user to build a good model.
  - ◆ Does it prevent nonconvex problems because checking convexity is hard.
- Ease of use.

Introduction

Topic

Considerations  
about the forms

Conic optimization.  
A recap

Basic cone types

Comments

An illustrative  
example

Algorithms

Primal problem:

$$\begin{aligned}
 (CO_P) \quad & \min && c^T x \\
 & \text{st} && Ax = b, \\
 & && x \in \mathcal{K}_1 \times \mathcal{K}_2 \times \cdots \times \mathcal{K}_k,
 \end{aligned}$$

where each  $\mathcal{K}_k$  is a cone (closed, pointed and solid).

Dual problem:

$$\begin{aligned}
 (CO_P) \quad & \max && b^T y \\
 & \text{st} && A^T y + s = c, \\
 & && s \in \mathcal{K}_1^* \times \mathcal{K}_2^* \times \cdots \times \mathcal{K}_k^*,
 \end{aligned}$$

where each  $\mathcal{K}_k^*$  is the dual convex cone i.e.

$$\mathcal{K}_k^* \equiv \{s : x^T s \geq 0, \forall x \in \mathcal{K}\}.$$

Introduction

Topic

Considerations  
about the forms

Conic optimization.  
A recap

Basic cone types

Comments

An illustrative  
example

Algorithms

## ■ Linear:

$$\mathcal{K}_l := \{x \in R : x \geq 0\}$$

## ■ Quadratic:

$$\mathcal{K}_q := \left\{ x \in R^n : x_1 \geq \sqrt{\sum_{j=2}^n x_j^2} \right\}$$

Introduction

Topic

Considerations

about the forms

Conic optimization.

A recap

Basic cone types

**Comments**

An illustrative  
example

Algorithms

- We will only deal with the above 2 **self-dual** cones.
- A quote from Stephen Boyd of Stanford: "Almost all convex optimization problem can be formulated using a combination of linear, quadratic, semi-definite and the exponential cones".
- See also the book of Ben-Tal and Nemirovski for conic quadratic representable sets.

## **An illustrative example**

Introduction

An illustrative  
example

Convex quadratic  
optimization

example continued

Practical issues

Algorithms

Functional formulation:

$$\begin{aligned} \min \quad & \frac{1}{2}x^T Qx + c^T x \\ \text{st} \quad & Ax = b, \\ & x \geq 0. \end{aligned}$$

Given convexity then there exists a  $H$  such that

$$Q = HH^T.$$

Conic reformulation

$$\begin{aligned} \min \quad & \frac{1}{2}t + c^T x \\ \text{st} \quad & Ax = b, \\ & H^T x - y = 0, \\ & s = 1, \\ & \|y\|^2 \leq 2st, \\ & x \geq 0. \end{aligned}$$

Introduction

An illustrative  
example

Convex quadratic  
optimization

example continued

Practical issues

Algorithms

- Conic reformulation requires more constraints and variables.
- The addition is highly structured and sparse.
- Conic form is convex by construction.
  - ◆  $Q$  is frequently negative semi-definite due to rounding errors or mistakes. How to deal with:

$$\begin{bmatrix} 1 & 1 \\ 1 & 1 - \epsilon \end{bmatrix} ?$$

- In practice  $Q$  is frequently low rank and dense. Implying the conic reformulation requires much less space to store.

Introduction

An illustrative  
example

Convex quadratic  
optimization  
example continued

**Practical issues**

Algorithms

- Many users of the nonlinear capabilities in MOSEK:
  - ◆ Do believe their nonlinear problems are convex.
  - ◆ Do believe convexity is not important.
  - ◆ Almost always make mistakes. (Errors in function or gradient computations).
  
- Checking and verifying convexity is an issue even for quadratic problems.
  
- Checking convexity and smoothness for arbitrary black box functions are hard.
  
- Data for the conic form is very simple. Just vectors, matrices and list of indexes.

# Algorithms

Properties of the  
search direction

Summary about  
algorithms

- The available algorithms determines which form is preferable.
- Only primal-dual interior-point algorithms are considered.
- They are efficient in practice.
- Polynomial complexity holds:
  - ◆ For some problems on functional form.
  - ◆ All conic quadratic problems.
- Claim: The algorithm for problems on conic form is more efficient and robust than problems on functional form.
- Justification of claim: Follows.

## Lagrange function

$$L(x, y) \equiv c(x) - y^T a(x),$$

where  $y \geq 0$ .

The dual problem:

$$\begin{aligned} \max \quad & L(x, y) - x^T s \\ \text{st} \quad & \nabla_{(x)} L(x, y)^T = s, \\ & x, y, s \geq 0, \end{aligned}$$

$s \in \mathbf{R}^n$ .

Alternatively:

$$\begin{aligned} \max \quad & L(x, y) - \nabla_x L(x, y)x \\ \text{st} \quad & \nabla_x L(x, y)^T = s, \\ & x, y, s \geq 0. \end{aligned}$$

 & \text{st} && a(x) = z, \\
 & && \nabla_x L(x, y)^T = s, \\
 & && x, z, y, s \geq 0.
 \end{aligned}$$

where  $z \in \mathbf{R}^m$  is slack variables.

Note:

- The KKT conditions is a monotone complementarity problem.
- Primal-dual interior-point type algorithm.
- Difficulties with detecting infeasibility!
- Feasibility constraints are potentially highly nonlinear!

Summary about algorithms

The homogeneous model denoted (*HMCP*):

$$\begin{aligned}
 \min \quad & (x; \tau)^T (s; \kappa) \\
 \text{st} \quad & \tau a(x/\tau) = z, \quad \text{primal feasibility} \\
 & \tau \nabla_x L(x/\tau, y/\tau)^T = s, \quad \text{dual feasibility,} \\
 & -x^T \nabla_x L(x/\tau, y/\tau)^T - y^T a(x/\tau) = \kappa, \quad \text{zero gap,} \\
 & x, z, \tau, s, y, \kappa \geq 0.
 \end{aligned}$$

- Has two additional variables  $\tau, \kappa$  and one additional constraint.
- (*HMCP*) is a homogeneous monotone complementarity problem.
- Always has solution (0).

**Theorem:** (Andersen and Ye 95)

Let  $(x^*, z^*, y^*, \tau^*, s^*, \kappa^*)$  be a maximal complementarity solution to  $(HMCP)$ . Then  $(MCP)$  has a solution if and only if  $\tau^* > 0$ . In this case,  $(x^*, z^*, y^*, s^*)/\tau^*$  is a complementarity solution for  $(MCP)$ .

**Conclusion:** Compute a maximal solution to  $(HMCP)$ .

Properties of the search direction

Summary about algorithms

Algorithm: Apply a primal-dual interior-point method to (*HMCP*) i.e. apply Newton's method to the perturbed optimality conditions:

$$\begin{aligned} \tau \nabla_x L(x/\tau, y/\tau)^T &= s, \\ \tau a(x/\tau) &= z, \\ -x^T \nabla_x L(x/\tau, y/\tau)^T - y^T a(x/\tau) &= \kappa, \\ Xs &= \mu e, \\ Zy &= \mu e, \\ \tau \kappa &= \mu, \\ x, z, \tau, s, y, \kappa &> 0. \end{aligned}$$

$\mu > 0$ : Is a parameter.

- Primal feasibility cond. is nonlinear.
- Dual feasibility cond. is nonlinear.
- Perturbed complementarity cond. is nonlinear.

Properties of the search direction

Summary about algorithms

- $\eta = (\gamma - 1)$  where  $\gamma \in [0, 1]$  is an algorithmic parameters.

### Step 4: Update.

$$(x^+; \tau^+; y^+; ) = (x; \tau; y) + \alpha(d_x; d_\tau; d_y)$$

### Update of slacks:

$$(z^+; s^+; \kappa^+) = (z + \alpha d_z; s + \alpha d_s; \kappa + \alpha d_\kappa)$$

or

$$z^+ = ((1 + \alpha\eta)r_P + \tau^+ a(x^+/\tau^+),$$

$$s^+ = ((1 + \alpha\eta)r_D + g^+),$$

$$\kappa^+ = ((1 + \alpha\eta)r_G + g_\kappa^+),$$

where

$$g^+ \equiv \tau^+ \nabla_x L(x^+/\tau^+, y^+/\tau^+)^T$$

$$g_\kappa^+ \equiv -(x^+)^T \nabla_x L(x^+/\tau^+, y^+/\tau^+)^T - (y^+)^T a(x^+/\tau^+)$$

## The nonlinear update

A primal-dual algorithm for conic quadratic problems

One iteration

Properties of the search direction

Summary about algorithms

- Alternative. A linear update

$$\begin{aligned}z^+ &= x + \alpha d_z, \\s^+ &= s + \alpha d_s \\ \kappa^+ &= \kappa + \alpha d_\kappa\end{aligned}$$

but then a merit function is required e.g. two norm of the residuals.

- Works most of the time.
- Can lead to very slow convergence and robustness problems.
- A major weakness.
- Nonlinear primal and dual feasibility constraints are the cause of the problems.

The homogeneous model:

$$\begin{aligned}
 (H) \quad Ax - b\tau &= 0, \text{ (primal feasibility)} \\
 A^T y + s - c\tau &= 0, \text{ (dual feasibility)} \\
 -c^T x + b^T y - \kappa &= 0, \text{ (zero gap)} \\
 (x; \tau) \in \mathcal{K}, (s; \kappa) \in \mathcal{K}
 \end{aligned}$$

- In linear case suggested suggested Goldman and Tucker. Later rediscovered by Mizuno, Todd and Ye.
- All solutions satisfies:  $x^T s + \tau \kappa = 0$ .
- If and only if  $\tau > 0$ , then an optimal solution exists.
- Find a solution such that  $\tau + \kappa > 0$ .
- Linear primal and dual feasibility conditions!!!
- Algorithmic framework: The Nesterov-Todd direction

Properties of the search direction

Summary about algorithms

Fact:

$$\begin{aligned}
 Ax^+ - b\tau^+ &= (1 + \alpha\eta)(Ax - b\tau), \\
 A^T y^+ + s^+ - c\tau^+ &= (1 + \alpha\eta)(A^T y + s - c\tau), \\
 -c^T x^+ + b^T y^+ - \kappa^+ &= (1 + \alpha\eta)(-c^T x + b^T y - \kappa), \\
 d_x^T d_s^T + d_\tau d_\kappa &= 0, \\
 (x^+)^T s^+ + \tau^+ \kappa^+ &= (1 + \alpha\eta)((x)^T s + \tau\kappa).
 \end{aligned}$$

Observations:

- NT search direction can be seen as Newtons method.
- The method is symmetric!
- The complementarity gap is reduced by a factor of  $(1 + \alpha\eta) \in [0, 1)$ .
- The infeasibility is reduced by the same factor.
- **No merit function is required.**

The nonlinear update

A primal-dual algorithm for conic quadratic problems

One iteration

Properties of the search direction

Summary about algorithms

- Both algorithms are called primal-dual interior-point.
- Only in the conic form are the feasibility constraints linear.
- The functional one is more like primal algorithm for the KKT system
- The conic algorithm is truly symmetric i.e. you can flip the primal and dual problem.
- Due to issues with the merit function then the functional form is not as robust as conic one.

- Performance on the functional formulation is bad.
- Merit function forces the alg. to take small steps.
- Behavior seen occasionally on large instances.
- Other interior-point optimizers may do better of course.

algorithms

The (restricted) conic formulation of nonlinear problems is advantageous because

- The problem data is simpler to deal in a software sense and no blackbox functions are required.
- It is impossible to formulate nonconvex problems.
- The available algorithm is much better.
- It easy to dualize the conic formulation.

Caveats:

- The conic formulation is usually bigger in terms of number of variables and constraints but also highly structured.
- Usually the storage and time spend per iteration will be same or less for the conic formulation.
