

# **Semidefinite Optimization using MOSEK**

Joachim Dahl

ISMV Berlin, August 23, 2012

## Introduction

Semidefinite  
optimization

Algorithms

Results and  
examples

Summary

- MOSEK is a state-of-the-art solver for large-scale linear and conic quadratic problems.
- Based on the homogeneous model using Nesterov-Todd scaling.
- Next version includes **semidefinite optimization**.
- Goal for first version is to beat SeDuMi.

## Why SDP in MOSEK?

- It is very powerful and flexible for modeling.
- We want the SDP work you developed to be available to our customers!
- Customers have been asking about it for awhile.

# Semidefinite optimization

■ Primal and dual problems:

$$\begin{aligned} & \text{minimize} && \sum_{j=1}^p C_j \bullet X_j \\ & \text{subject to} && \sum_{j=1}^p A_{ij} \bullet X_j = b_i \\ & && X_j \in \mathcal{S}_+^{n_j}, \end{aligned}$$

$$\begin{aligned} & \text{maximize} && b^T y \\ & \text{subject to} && \sum_{i=1}^m y_i A_{ij} + S_j = C_j \\ & && S_j \in \mathcal{S}_+^{n_j}, \end{aligned}$$

where  $A_{ij}, C_j \in \mathcal{S}^{n_j}$ .

■ Optimality conditions:

$$\sum_{j=1}^p A_{ij} \bullet X_j = b_i, \quad \sum_{i=1}^m y_i A_{ij} + S_j = C_j, \quad X_j S_j = 0, \quad X_j, S_j \in \mathcal{S}_+^{n_j}.$$

■ Equivalent complementary conditions if  $X_j, S_j \in \mathcal{S}_+^{n_j}$ :

$$X_j \bullet S_j = 0 \quad \iff \quad X_j S_j = 0 \quad \iff \quad X_j S_j + S_j X_j = 0.$$

# Algorithms

For symmetric matrices  $U \in \mathcal{S}^n$  we define

$$\mathbf{svec}(U) = (U_{11}, \sqrt{2}U_{21}, \dots, \sqrt{2}U_{n1}, U_{22}, \sqrt{2}U_{32}, \dots, \sqrt{2}U_{n2}, \dots, U_{nn})^T$$

with inverse operation

$$\mathbf{smat}(u) = \begin{bmatrix} u_1 & u_2/\sqrt{2} & \cdots & u_n/\sqrt{2} \\ u_2/\sqrt{2} & u_{n+1} & \cdots & u_{2n-1}/\sqrt{2} \\ \vdots & \vdots & & \vdots \\ u_n/\sqrt{2} & u_{n-1}/\sqrt{2} & \cdots & u_{n(n+1)/2} \end{bmatrix},$$

and a symmetric product

$$u \circ v := (1/2)(\mathbf{smat}(u)\mathbf{smat}(v) + \mathbf{smat}(v)\mathbf{smat}(u)).$$

Let

$$a_{ij} = \text{svec}(A_{ij}), \quad c_j := \text{svec}(C_j), \quad x_j := \text{svec}(X_j), \quad s_j := \text{svec}(S_j),$$

and

$$A := \begin{bmatrix} a_{11}^T & \cdots & a_{1p}^T \\ \vdots & & \vdots \\ a_{m1}^T & \cdots & a_{mp}^T \end{bmatrix}, \quad c := \begin{bmatrix} c_1 \\ \vdots \\ c_p \end{bmatrix}, \quad x := \begin{bmatrix} x_1 \\ \vdots \\ x_p \end{bmatrix}, \quad s := \begin{bmatrix} s_1 \\ \vdots \\ s_p \end{bmatrix}.$$

We then have primal and dual problems:

$$\begin{array}{ll} \text{minimize} & c^T x \\ \text{subject to} & Ax = b \\ & x \succeq 0, \end{array}$$

$$\begin{array}{ll} \text{maximize} & b^T y \\ \text{subject to} & A^T y + s = c \\ & s \succeq 0. \end{array}$$

Simplified homogeneous model:

$$\begin{bmatrix} s \\ 0 \\ \kappa \end{bmatrix} + \begin{bmatrix} 0 & A^T & -c \\ A & 0 & -b \\ c^T & -b^T & 0 \end{bmatrix} \begin{bmatrix} x \\ y \\ \tau \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \quad x, s \succeq 0, \tau, \kappa \geq 0.$$

Note that  $(x, y, s, \kappa, \tau) = 0$  is feasible, and  $x^T s + \kappa \tau = 0$ .

- If  $\tau > 0, \kappa = 0$  then  $(x, y, s)/\tau$  is a primal-dual optimal solution,

$$Ax = b\tau, \quad A^T y + s = c\tau, \quad x^T s = 0.$$

- If  $\kappa > 0, \tau = 0$  then either primal or dual is infeasible,

$$Ax = 0, \quad A^T y + s = 0, \quad c^T x - b^T y < 0,$$

Primal infeasible if  $b^T y > 0$ , dual infeasible if  $c^T x < 0$ .

Summary

We define the central path as:

$$\begin{bmatrix} s \\ 0 \\ \kappa \end{bmatrix} + \begin{bmatrix} 0 & A^T & -c \\ A & 0 & -b \\ c^T & -b^T & 0 \end{bmatrix} \begin{bmatrix} x \\ y \\ \tau \end{bmatrix} = \gamma \begin{bmatrix} A^T y^{(0)} + s^{(0)} - c\tau^{(0)} \\ Ax^{(0)} - b\tau^{(0)} \\ c^T x^{(0)} - b^T y^{(0)} + \kappa^{(0)} \end{bmatrix}$$

$$x \circ s = \gamma \mu^{(0)} e, \quad \tau \kappa = \gamma \mu^{(0)},$$

where  $\gamma \in [0, 1]$ ,  $\mu^{(0)} = \frac{(x^{(0)})^T s^{(0)} + \kappa^{(0)} \tau^{(0)}}{n+1} > 0$  and

$$e = \begin{bmatrix} \text{svec}(I_{n_1}) \\ \vdots \\ \text{svec}(I_{n_p}) \end{bmatrix}.$$

Summary

A primal-dual scaling is defined by a non-singular  $R_k$  as

$$W_k(x_k) := \text{svec}(R_k^{-T} X_k R_k^{-1}), \quad W_k^{-T}(s_k) := \text{svec}(R_k S_k R_k^T),$$

- preserves the semidefinite cone,

$$x_k \succ 0, s_k \succ 0 \iff W_k(x_k) \succ 0, W_k^{-T}(s_k) \succ 0,$$

- the central path,

$$x_k \circ s_k = \gamma \mu e_k \iff W_k(x_k) \circ W_k^{-T}(s_k) = \gamma \mu e_k,$$

- and the complementarity:  $x_k^T s_k = W_k(x_k)^T W_k^{-T}(s_k)$ .

Summary

- Helmberg-Kojima-Monteiro (HKM)  $R_k^{-1} = S_k^{1/2}$ :

$$W_k(x_k) = \text{svec}(S_k^{1/2} X_k S_k^{1/2}), \quad W_k^{-T}(s_k) = e_k.$$

- Nesterov-Todd (NT):

$$R_k^{-1} = \left( S_k^{-1/2} (S_k^{1/2} X_k S_k^{1/2})^{1/2} S_k^{-1/2} \right)^{1/2},$$

Satisfies  $R_k^{-1} X_k R_k^{-1} = R_k S_k R_k$ . Computed as:

$$R_k^{-1} = \Lambda^{1/4} Q^T L^{-1}, \quad LL^T = X_k, \quad Q\Lambda Q^T = L^T S_k L$$

which satisfies  $R_k^{-T} X_k R_k^{-1} = R_k S_k R_k^T = \Lambda_k$ .

Summary

## Linearizing the scaled centrality condition

$$W_k(x_k) \circ W_k^{-T}(s_k) = \gamma\mu e_k$$

and discarding higher-order terms leads to

$$\Delta x_k + \Pi_k \Delta s_k = \gamma\mu s_k^{-1} - x_k,$$

where

- HKM scaling:  $\Pi_k z_k = \text{svec}(X_k Z_k S_k^{-1} + S_k^{-1} Z_k X_k) / 2,$
- NT scaling:  $\Pi_k z_k = \text{svec}(R_k^T R_k Z_k R_k^T R_k).$

Most expensive part of interior-point optimizer is solving:

$$\begin{aligned}
 A\Delta x - b\Delta\tau &= (\gamma - 1)(Ax - b\tau) && = r_1 \\
 A^T \Delta y + \Delta s - c\Delta\tau &= (\gamma - 1)(A^T y + s - c\tau) && = r_2 \\
 c^T \Delta x - b^T \Delta y + \Delta\kappa &= (\gamma - 1)(c^T x - b^T y + \kappa) && = r_3 \\
 \Delta x + \Pi\Delta s &= \gamma\mu s^{-1} - x && = r_4 \\
 \Delta\kappa + \kappa/\tau\Delta\tau &= \gamma\mu/\tau - \kappa && = r_5
 \end{aligned}$$

Gives constant decrease in residuals and complementarity:

$$\begin{aligned}
 A(x + \alpha\Delta x) - b(\tau + \alpha\Delta\tau) &= (1 - \alpha(1 - \gamma))(Ax - b\tau) \\
 (x + \alpha\Delta x)^T (s + \alpha\Delta s) + (\kappa + \alpha\Delta\kappa)(\tau + \alpha\Delta\tau) &= \underbrace{(1 - \alpha(1 - \gamma))}_{<1} (x^T s + \kappa\tau).
 \end{aligned}$$

Polynomial complexity for  $\gamma$  chosen properly.

After block-elimination, we get a  $2 \times 2$  system:

$$\begin{aligned} A\Pi A^T \Delta y - (A\Pi c + b)\Delta\tau &= r_y \\ (A\Pi c - b)\Delta y + (c^T \Pi c + \kappa/\tau)\Delta\tau &= r_\tau. \end{aligned}$$

We factor  $A\Pi A^T = LL^T$  and eliminate

$$\Delta y = L^{-T} L^{-1} ((A\Pi c + b)\Delta\tau + r_y).$$

Then

$$\begin{aligned} ((A\Pi c - b)^T L^{-T} L^{-1} (A\Pi c + b) + (c^T \Pi c + \kappa/\tau)) \Delta\tau &= \\ r_\tau - (A\Pi c - b)^T L^{-T} L^{-1} r_y. \end{aligned}$$

An extra (insignificant) solve compared to an infeasible method.

Schur complement computed as a sum of outer products:

$$\begin{aligned}
 A\Pi A^T &= \begin{bmatrix} a_{11}^T & \dots & a_{1p}^T \\ \vdots & & \vdots \\ a_{m1}^T & \dots & a_{mp}^T \end{bmatrix} \begin{bmatrix} \Pi_1 & & \\ & \ddots & \\ & & \Pi_p \end{bmatrix} \begin{bmatrix} a_{11} & \dots & a_{m1} \\ \vdots & & \vdots \\ a_{1p} & \dots & a_{mp} \end{bmatrix} \\
 &= \sum_{k=1}^p P_k^T (P_k A_{:,k} \Pi_k A_{:,k}^T P_k^T) P_k,
 \end{aligned}$$

where  $P_k$  is a permutation of  $A_{:,k}$ . Complexity depends on choice of  $P_k$ .

We compute only  $\text{tril}(A\Pi A^T)$ , so by

$$\text{nnz}(P_k A_{:,k})_1 \geq \text{nnz}(P_k A_{:,k})_2 \geq \dots \geq \text{nnz}(P_k A_{:,k})_p,$$

get a good reduction in complexity. More general than SDPA.

To evaluate each term

$$a_{ik}^T \Pi_k a_{jk} = (R_k^T A_{ik} R_k) \bullet (R_k^T A_{jk} R_k) = A_{ik} \bullet (R_k R_k^T A_{jk} R_k R_k^T).$$

we follow SeDuMi. Rewrite

$$R_k R_k^T A_{jk} R_k R_k^T = \hat{M} M + M^T \hat{M}^T,$$

i.e., a symmetric (low-rank) product.

- $A_{ik}$  sparse: evaluate  $\hat{M} M + M^T \hat{M}^T$  element by element.
- $A_{ik}$  dense: evaluate  $\hat{M} M + M^T \hat{M}^T$  using level 3 BLAS.

May exploit low-rank structure later.

Additionally, the MOSEK solver

- uses Mehrotra's predictor-corrector step.
- solves mixed linear, conic quadratic and semidefinite problems.
- employs a presolve step for linear variables, which can reduce problem size and complexity significantly.
- scales constraints trying to improving conditioning of a problem.

**SDPLIB benchmark**

Profiling

Conic modeling

Summary

---

- We use the subset of SDPLIB used by H. D. Mittelmann for his SDP solver comparison.
- For brevity we report only iteration count, computation time, and relative gap at termination.
- Our SDPA-format converter detects block-diagonal structure within the semidefinite blocks (SeDuMi and SDPA does not), so for a few problems our solution time is much smaller.
- All solvers run on a single thread on an Intel Xeon E32270 with 4 cores at 3.4GHz and 32GB memory using Linux.

Semidefinite  
optimization

Algorithms

Results and  
examples

SDPLIB benchmark

Profiling

Conic modeling

Summary

- Forming  $A\Pi A^T$  (Schur) is not always most expensive step (as perhaps believed).
- A good parallelization speedup is possible for computing  $A\Pi A^T$ . (Factor is already parallelized).
- The update step (updating variables, neighborhood check, new NT scaling) is very cheap for LP and SOCP, but expensive for SDP, mainly due to NT scaling; HKM scaling would give an improvement.
- Stepsize computations (e.g., stepsize to boundary) are moderately expensive, but hard to speed up.

Profiling

**Conic modeling**

Summary

For  $A \in \mathcal{S}^n$ , the nearest correlation matrix is

$$X^* = \arg \min_{X \in \mathcal{S}_+^n, \text{diag}(X)=e} \|A - X\|_F.$$

Conic formulation exploiting symmetry of  $A - X$ :

$$\begin{aligned} & \text{minimize} && t \\ & \text{subject to} && \|z\|_2 \leq t \\ & && \text{svec}(A - X) = z \\ & && \text{diag}(X) = e \\ & && X \succeq 0. \end{aligned}$$

Simple formulation on paper, but complicated to formulate in “standard form” as in SeDuMi, SDPA, ...

Conic modeling

Summary

- For conic modeling you need a modeling tool!
- Nice MATLAB toolboxes exist (Yalmip, CVX, ...), but not for other languages.
- We developed a modeling API called MOSEK Fusion:
  - ◆ A tool for self-dual conic modeling; no QP or general convex optimization.
  - ◆ Idea: create and manipulate linear expressions, and assign them to different cones. Simple but flexible design; scales well for large problems.
  - ◆ Available for Python, Java, .NET. Planned versions include MATLAB (soon), C++ (later).
  - ◆ Syntax almost identical across platforms.

```

def svec(e):
    N = e.get_shape().dim(0)
    S = Matrix.sparse(N * (N+1) / 2,
                     N * N,
                     range(N * (N+1) / 2),
                     [ (i+j*N) for j in xrange(N) for i in xrange(j,N) ],
                     [ (1.0 if i == j else 2**(0.5)) for j in xrange(N) for i in xrange(j,N) ])

    return Expr.mul(S, Expr.reshape( e, N * N ))

def nearestcorr(A):
    M = Model("NearestCorrelation")
    N = len(A)

    # Setting up the variables
    X = M.variable("X", Domain.inPSDCone(N))

    # t > || z ||_2
    tz = M.variable("tz", Domain.inQCone(N*(N+1)/2+1))
    t = tz.index(0)
    z = tz.slice(1, N*(N+1)/2+1)

    # svec (A-X) = z
    M.constraint( Expr.sub(svec(Expr.sub(DenseMatrix(A), X)), z), Domain.equalsTo(0.0) )

    # diag(X) = e
    for i in range(N):
        M.constraint( X.index(i,i), Domain.equalsTo(1.0) )

    # Objective: Minimize t
    M.objective(ObjectiveSense.Minimize, t)
    M.solve()

```

Summary

---

References

- SDP solver in MOSEK 7.0 based on self-dual homogeneous embedding and NT scaling.
- Faster than SeDuMi, comparable with SDPA.
- Includes `Fusion`, a powerful tool for self-dual conic modeling.
- Future directions:
  - ◆ Incorporate multithreading.
  - ◆ Exploit low-rank structure in data.
  - ◆ Possibly implement the HKM direction.
